

What is a Subquery

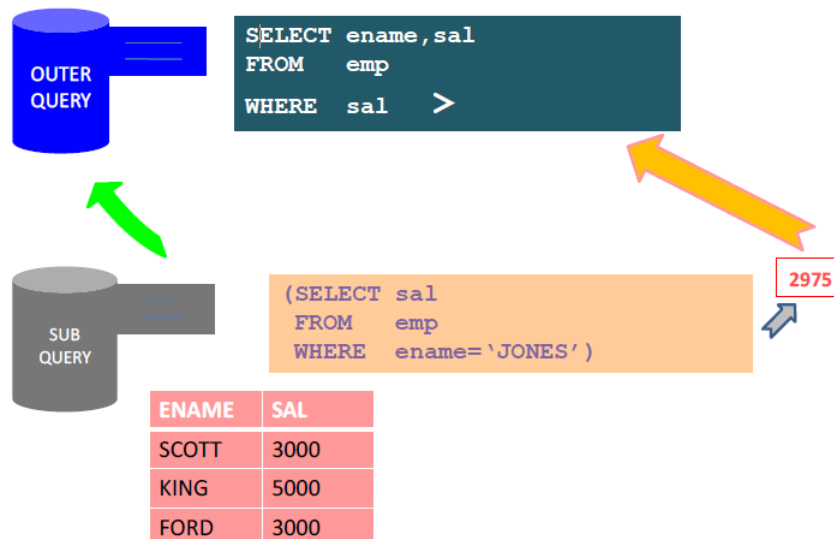

A subquery is a SELECT statement embedded in a clause of another SQL statement.

Types of Subquery

1. SINGLE ROW

Inner Query returns a single row which in turn can be used to return multiple rows as per the where clause.

2. MULTIPLE ROW

Inner Query returns multiple rows. We cannot use an equal operator in case of multiple rows being returned by the subquery.

mysql> select ename,sal

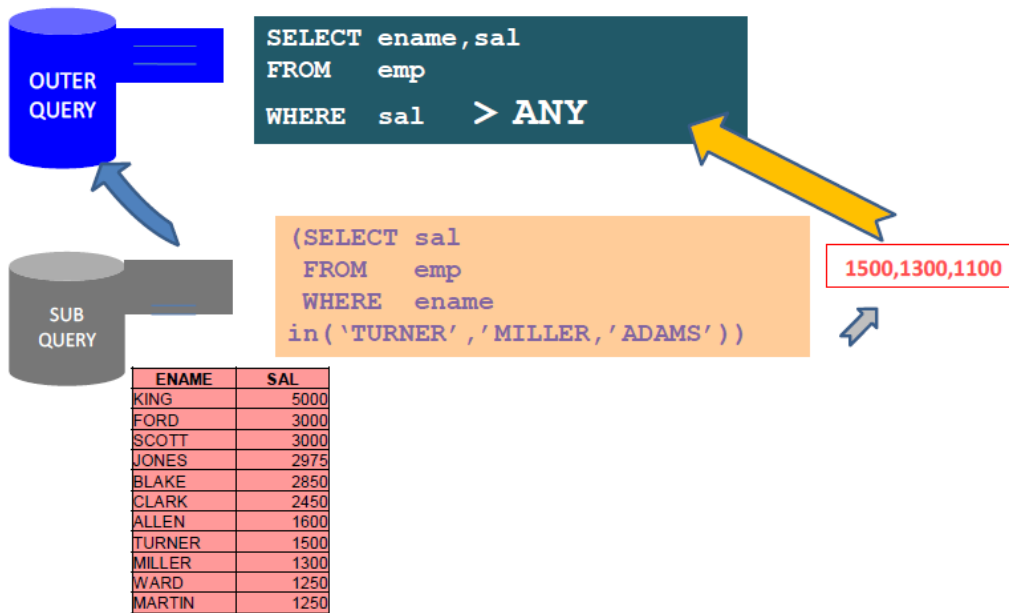

-> from emp

-> where sal IN (select sal from emp

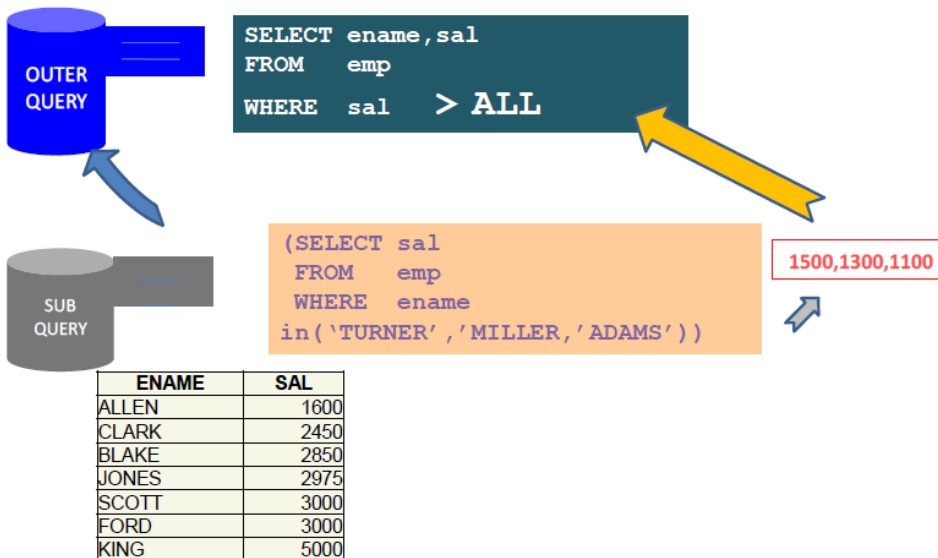

-> where ename in('WARD','MARTIN'));

SUBQUERY	OPERATORS
SINGLE ROW	=,<,>,<=,>=,<>
MULTIPLE ROW	IN,NOT IN,ANY,ALL

Multiple row subquery using **ANY**

Multiple row subquery using **ALL**

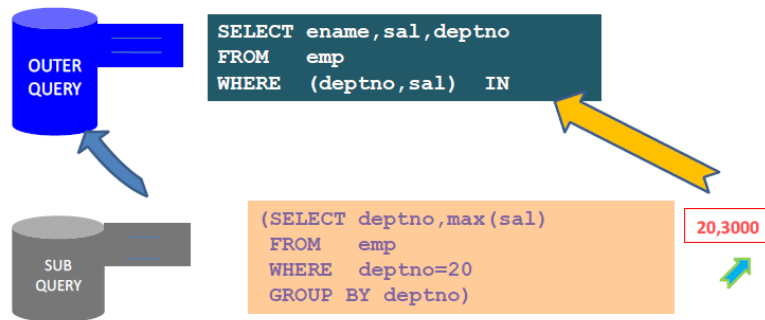

3. MULTIPLE COLUMN

Subqueries so far seen were returning single row/multiple row but ONLY ONE COLUMN. Here is a subquery which gives 2 columns.

```
mysql> select max(sal),deptno
-> from emp
-> group by deptno;
```

Multiple COLUMN subquery

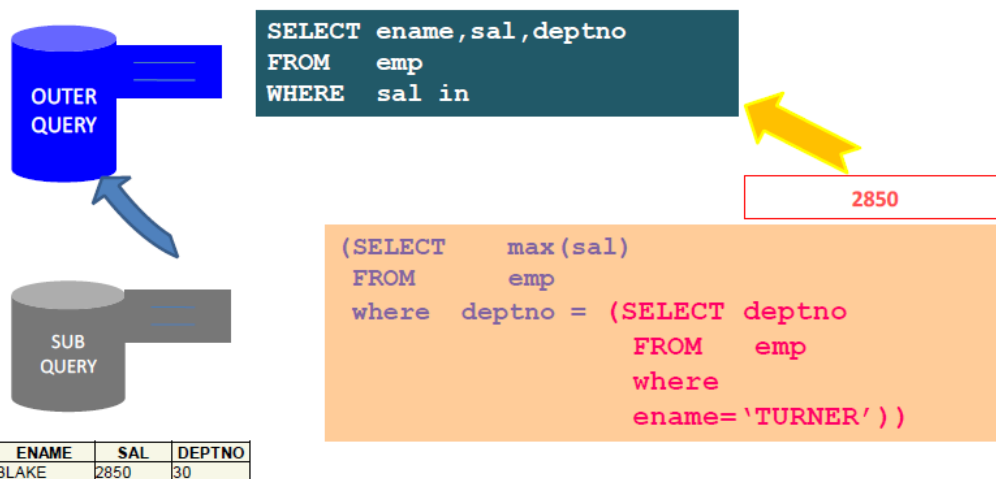

ENAME	SAL	DEPTNO
FORD	3000	20
SCOTT	3000	20

4. NESTED

Subquery can return a single row, multiple rows with a single column or multiple columns. It may be required that the subquery itself needs another subquery which we refer to as a nested query.

NESTED subquery

ENAME	SAL	DEPTNO
BLAKE	2850	30

5. CORRELATED

The correlation comes from the fact that the subquery uses information from the outer query and the subquery executes once for every row in the outer query. We can easily write employees who are taking salaries more than the average salary of the entire table.

Correlated subquery
